

If you are creating a logo, you would need to use the exact colours. Download the logo, import it or drag it onto the pasteboard. In the colour picker menu, below the opacity slider is the dropper. Click on it and then go over to the logo and click on the desired colour. That colour will automatically be updated on your object.

Note the HSB and Hex values. You will need to give them to the developer when handing over the design.

A gradient is a combination of two or more colors blending into each other. You may need to use this feature to create a more vibrant design. The only difference between a linear and a radial gradient is that linear shades from the starting point to the ending point in a straight line whereas radial does the same in a circular pattern. When you select radiant, a gradient stripe appears below the drop down menu. You can determine the colours on this stripe. A line (linear gradient) or circle (radial gradient) will also appear on the object. Any change you make in the colour picker will also be applied to the object simultaneously so you can see the effect. The line or circle can be moved as per your choice.

On the gradient stripe, there are two points at the far ends. These are the colour markers. Click on one of the markers and select a colour using the colour field, shade card and opacity slider. You can also add in more markers by just clicking on the stripe. The position of the marker can also be changed either in the stripe or on the object. To remove a marker, click on the marker on the stripe and drag it outside or select it on the object and hit delete. Add in the gradient style to your assets for further use.

Change the direction of linear gradient with the end of line points and the drag the corner handle to change the orientation point and the angle of radial gradients. You can also drag the end-points of the on-canvas gradient editor segment outside the bounds of the object. If a color stop is placed outside the bounds of an object, the color (associated with the color stop) is not shown on the object.

Earlier, you did a simple drag and drop to import pictures into your XD file. You can also copy the picture and paste it or use the Import functionality under the hamburger menu. XD supports the import of various file formats like PNG, JPG, TIFF, GIF, or SVG. If you are looking to insert a logo in your file, you can copy it directly from the web browser and paste it on your pasteboard. Simple and effective, right? Now, if you have been using Photoshop or Illustrator or Sketch and want to use those images here, that's the easiest thing in the world. You don't have to re-create them
