

the apk folder located inside and you will see a few files and folders in here. In the main ApkTool folder, change the extension of the DefaultTheme file from .apk to .zip. Open it with WinRAR and you will see a bunch of files and folders, amongst them META-Inf and AndroidManifest.xml files. Extract these files to the newly created build/apk folder (you will be replacing the AndroidManifest.xml file). Run the build command for DefaultTheme in the command prompt again. The new apk file will be created inside the newly created 'dist' folder. Replace this file in the system/app folder in the working folder.

Editing 9.png file

Some of the image files in the ROM are in the form of 9.png. These are slightly tricky than simply png files. But editing these adds some more oomph to your ROM.

Copy the SystemUI.apk file to the ApkTool folder. Decompile this file using the command prompt. Open the res folder and open the drawable folder. Copy any 9.png file to a folder of your choice. Look at the dimensions of your 9.png file and the image file you want. To resize your file to the 9.png file, open it with GIMP. go to Images menu and click on Scale Image. Enter in the new dimensions and click

Scale. Save and close the file. Select both the 9.png file and your file and open with GIMP. Go to your image file, zoom in and select the Rectangular Select tool. Leave 1 pixel border on all sides, select the image and cut it. Go to the 9.png file and again follow the above process without the cut. Instead, delete the selection and paste the image cut earlier. When you save this file, a dialogue box will pop. click export and close it. Copy and replace this file to the original location in the SystemUI folder. Build the SystemUI folder

You can even include widgets to spice things up
