

Cygwin

Remember, when you started building your ROM, you had to change the updater-script to update-script? Now we need to change the update-script back to updater-script. As you have already seen, this is the most important file you need to flash your ROM on to the device.

Open cygwin and open the kitchen menu (type ./menu). Go to advanced options (type O) and type 23 then 2 (change update-script to updater-script).. Once this is done, you are ready to build the ROM. Type in the option 99 (building the ROM) and then hit enter every time it asks you a question. Enter will select the default values. At this point, till you get more experience on this front, don't mess around with them. Once you're more used to Android customisations and know what you're dealing with, then you can feel free to play around with these values.

At the end of it you will see that an update.zip file is created. You can sign your ROM if you wish to and rename the zip file (enter .zip extension to the file). The newly created ROM zip file is located in the OUTPUT_ZIP folder in the kitchen folder.

Congratulations! You have created your own custom ROM. Copy this file on to your device and boot your device in recovery mode. On the TWRP screen, click on Install and navigate to the file. The ROM will automatically install and you are the new proud owner of your own ROM.

The ROM files need to be "packaged" in a specific way so that the build is perfect
