

mation about ccache on Google's Android build environment initialisation page.

You can also enable the optional ccache compression. While this may involve a slight performance slowdown, it increases the number of files that fit in the cache. To enable, run:

- `export CCACHE_COMPRESS=1`
or add that line to your `~/.bashrc` file.

Configure jack

Jack is the currently used Java tool-chain for building LineageOS 14.1 and above. It is known to run out of memory often if not configured correctly. This can be fixed quite simply by running this command:

- `export ANDROID_JACK_VM_ARGS="-Dfile.encoding=UTF-8 -XX:+TieredCompilation -Xmx4G"`

Adding that command to your `~/.bashrc` file will automatically configure Jack to allocate a sufficient amount of memory (in this case, 4GB).

Start the build

To start building, type:

- `croot`
- `brunch cheeseburger`

The build should begin.

Install the build

Assuming the build completed without errors (it will be obvious when it finishes), type the following in the terminal window the build ran in:

- `cd $OUT`

NOTE

If compression is enabled, the ccache size can be lower (aim for approximately 20GB for one device).

Make sure you have enough storage before you start off. An SSD will result in a faster build process
