

Again, we remind you that you assume all risk of trying this and there is a chance that you will brick your phone and shed a few tears and even pull your hair out, but the reward makes it worth it. Let's begin!

What you'll need

- A OnePlus X
- A 64-bit computer, either Linux, OS X, or Windows is fine. You'll also need a reasonable amount of RAM. 8GB should suffice, but remember, the lower the RAM, the longer the build will take. About 100 GB of free storage. Using SSDs is preferable for considerably faster build times.
- A USB data cable compatible with the OnePlus X
- A good enough internet connection with enough bandwidth to download the entire git project.
- Obviously, you need to be familiar with Android phones and how they work. Installing custom ROMs, unlocking the bootloader and rooting your phone are great ways to jump into this scene. You might want to familiarise yourself with Github so that you can organise your build process.

TIP

Most build instructions are in Linux which is why we'd advised you to install cygwin in our previous chapters because it brings the Linux desktop environment to Windows. You can always download the latest Ubuntu installation from Ubuntu's website and install the same alongside Windows on your personal computer. Or you can even use pre-made images in virtual machines to run Ubuntu within Windows and still get the job done.

Build LineageOS and LineageOS Recovery

Install the SDK

If you haven't previously installed adb and fastboot, you can download them from Google. Extract it running:

- `unzip platform-tools-latest-linux.zip -d ~`

Now you have to add adb and fastboot to your PATH. Open ~/.profile and add the following:

- `# add Android SDK platform tools to path`
- `if [ -d "$HOME/platform-tools" ] ; then`
