

- `PATH="$HOME/platform-tools:$PATH"`
- `fi`

Then, run `source ~/.profile` to update your environment.

Install the build packages

Like all complex software, several packages are needed to build LineageOS.

You can install these using your Linux distribution's package manager.

To build LineageOS, you'll need:

- `bc bison build-essential ccache curl flex g++-multilib gcc-multilib git gnupg gperf imagemagick lib32ncurses5-dev lib32readline-dev lib32z1-dev libbsd-dev libbz2-dev libncurses5-dev libssl-dev libwxgtk3.0-dev libxml2 libxml2-utils lzop pngcrush rsync schedtool squashfs-tools xsltproc zip zlib1g-dev`

For Ubuntu versions older than 16.04 (xenial), substitute:

- `libwxgtk3.0-dev → libwxgtk2.8-dev`

Java

Different versions of LineageOS require different JDK (Java Development Kit) versions. Using the wrong JDK version generally will not be an issue as long as you are moving up a version. However, sometimes functions or methods can be deprecated and that will lead to errors. So it's best to stick with whatever Java version is recommended for the build.

- LineageOS 14.1-15.1: OpenJDK 1.8 (install `openjdk-8-jdk`)
- LineageOS 11.0-13.0: OpenJDK 1.7 (install `openjdk-7-jdk`)*

* Ubuntu 16.04 and newer do not have OpenJDK 1.7 in the standard package repositories. See the Ask Ubuntu question "How do I install openjdk 7 on Ubuntu 16.04 or higher?". Note that the suggestion to use PPA `openjdk-`

NOTE

The platform tools are only required for the very first time you are building a ROM. It's part of prepping your system for the custom ROM building process and need not be repeated.

TIP

Ubuntu Software Center is the package manager for Ubuntu, different Linux distros might call them by a different name. With bash, you can simply accomplish all of this using the `apt-get` command to get packages from the default repositories.
