

Caching in your ROM can make your phone much faster

devices, we'd recommend you to get an larger cache size of 75-100GB. Before you take this decision, keep in mind that the space you set aside will stay on your phone. See more information about ccache on Google's Android build environment initialization page.

You can also enable the optional ccache compression. While this may involve a slight performance slowdown, it increases the number of files that fit in the cache. To enable it, run the following command:

- `export CCACHE_COMPRESS=1`
or add that line to your `~/bashrc` file.

NOTE

If compression is enabled, the ccache size can be lower (aim for approximately 20GB for one device).

Configure jack

Jack, the currently most used toolchain in Java, is being used to build LineageOS 14.1 and up. As it happens, it does run out of memory often if not configured correctly - a simple fix is to run this command:

- `export ANDROID_JACK_VM_ARGS="-Dfile.encoding=UTF-8 -XX:+TieredCompilation -Xmx4G"`

Adding that command to your `~/bashrc` file will automatically configure Jack to allocate a sufficient amount of memory (in this case, 4GB).
