Downclock your SoC

There are times when your phone starts heating up a lot. There can be a multitude of reasons for this happening and one of the simplest solutions to resolve this is to downclock your phone by a bit. To do this, you will need a deodexed ROM. A deodexed ROM is simply easier to edit since the data that would ordinarily would be present in the .odex files would be integrated into the .apk themselves. Then you'll need a couple of files from an XDA thread which can be found here (<https://goo.gl/mzkzBM>).

Simply decompile the settings.apk file and navigate to res/values/strings.xml and change the below mentioned entries to:

- `<string name="cpu _ control">CPU Control</string>`
- `<string name="cpu _ control _ summary">Manage CPU frequencies and governor</string>`
- `<string name="cpu _ stats">CPU Stats</string>`
- `<string name="cpu _ stats _ summary">Monitor CPU usage</string>`
- `<string name="cpu _ setting _ header">System</string>`

Now, find another file which is present in res/xml/development_prefs and add the following command lines:

- `<PreferenceCategory android:title="@string/cpu _ setting _ header" android:key="cpu _ setting _ header">`
- `<PreferenceScreen android:title="@string/cpu _ control" android:key="cpu _ control" android:summary="@string/cpu _ control _ summary">`
- `<intent android:targetPackage="it.sineo.android.noFrills-`
