

mers save time and cut down on their initial development cycle. Almost all of the work done in the past on Python has been documented on libraries like PyPi, SciPy or NumPy. NumPy and SciPy are famous for their selection on scientific computing, while Django boasts of a fantastic collection of web development related coding. With a little more in-depth research, you will realise that there are libraries for almost every imaginable use case that you can encounter – image manipulation, server automation, scientific calculations, machine learning applications, natural language processing, etc.

Huge cloud media services like [Encoding.com](https://www.encoding.com) also allow for compatibility of Python with C-family languages. What this means is that there are library-like tools that offer the programmer with cross-platform support. And this one of the biggest benefits of working with Python.

Access to a healthy, active user community

Documentation as well as developer support can make or break a good programming language. Python is well-furnished as far as both these aspects as concerned. Given that it has been around for as long as it has been, it boasts of a huge archive of documentation over the decades. This coupled with the number of guides, tutorials and other study material available out there make it an easy bet for most programmers. Add to this the fact that as a community, the developer community for Python is pretty active. What this means for programmers is that they can get timely help whenever needed.

Corporate sponsorship matters

Having a corporate sponsor can possibly be the biggest help any programming language can ever have. C++ has Microsoft, PHP is used by Facebook, Java had Sun. Python was picked up by tech giant Google. Google adopted Python back in 2006 and have relied on it very heavily ever since. It features in a number of their applications as well as platforms.

Why is this important, you ask? It is because companies like Google want their future developers or potential teammates to work with their apps and systems. For this to work well, the onus lies on them at some level to provide resources. For Python, what this translates to is that Google has created a vast sea of guides and tutorials for working with Python. This contributes towards an already large yet ever-growing list of documentation and support tools for the language. It also helps provide free advertising for Python in the world of development and developers. It is a win-win situation for the Python programming language as well as Google themselves.
