

Encountering an error after hours of coding can be frustrating to say the least. Know thy enemy is the rule, so go through this chapter carefully

- `try:`
- `print(4 + spam3)`
- `except NameError:`
- `print("NameError Exception raised")`
- `finally:`
- `print("Code is good")`

As you can see, the `try` clause should raise an error. This will cause the `except` clause to be executed but since there is a `finally` clause also present, it will also be executed. So the output will read as

- `NameError Exception raised`
- `Code is good`

If there was no `except` clause present, only the output of the `finally` clause will be displayed. When an exception is thrown in the `try` block, the execution immediately passes to the `finally` block. After all the statements in the `finally` block are executed, the exception is raised again and is handled in the `except` statements if present in the next higher layer of the `try-except` statement. Also, you cannot use the `else` clause while using the `finally` clause.
