

Error and exception handling is essential to ensure that your code does not break due to unexpected factors

Here, we have defined a base class called `Error`. The other two exceptions (`ValueTooSmallError` and `ValueTooLargeError`) that are actually raised by our program are derived from this class. Now suppose we run a program that makes the user guess the number and throws exceptions when the value is incorrect.

```

• number = 10
•
• while True:
•     try:
•         i_num = int(input("Enter a number: "))
•         if i_num < number:
•             raise ValueTooSmallError
•         elif i_num > number:
•             raise ValueTooLargeError
•         break
•     except ValueTooSmallError:
•         print("This value is too small, try again!")
•         print()
•     except ValueTooLargeError:
•         print("This value is too large, try again!")

```
