

purpose - the readers remain readers, not doers. Easy to follow pictures of the process are indeed useful with hardware DIY projects, because the picture is only an image of the project - you'll be doing it yourself; but with software, a screenshot of the finished bug-free code is the final product itself. All that would be left to do is transcribing, and we're sure there are neural nets for that.

While reading the following, imagine you are the program you are writing to accomplish something. This chapter is the 'what' of it, you the DIY-er will be the 'how'.

To describe it pragmatically, instead of "Type the following and save it in a file called sayhello.py:

```
• person = input('Enter your name: ')
print('Hello', person)
• "
```

We would suffice to say " Ask for the user's name and say hello to them." It is your choice to accomplish it from a python console, one command at a time, or save it as a script and run it from the terminal. You can use your favourite IDE or even make yourself a venv if you want to. You may not get it working the first time, you will hopefully encounter hiccups and have to make multiple small efforts. Conquer your laziness as you will, we can't fight your battles.

That said, we CAN provide you strategy. You wouldn't be reading a DIY chapter unless you needed some minimal amount of hand holding. Fret not, we won't get too complex here, and even if we're not making you drink, we will certainly bring the water to you. You can apply the forms of your choice to the content. Feel free to improvise as you follow along, and if you think there is a better way to achieve something, we'd love to hear your thoughts in the forums. Once you're done you can share your code on the Digit forums, and help your fellow readers out. This way we can provide more value to you, our beloved readers. :)

We have covered Python based web-publishing technologies like Django in earlier FastTracks, so you can refer to that if you want to make any of the following into an accessible web app! You could even take it to the next level with using modules like Tkinter or urwid (pronounced er-wood) to make a standalone GUI application...

First things first though. Before Morrowind there were text based RPGs, and so shall you first build bare-boned CLI apps. Actually, before that, a
