

script. The main project for beginners is the first on the list- the web scraper. Following that there are some slightly more advanced (and very much more abstractly condensed) projects. So let's get started!

Pre-requisites

We're going to assume you didn't jump straight to this chapter, and if you did, it is because you already know your dunder. Just to be sure, you need to have the following prerequisites to continue:

- Basic python syntax, structure, and usage. Control flow (conditions, loops) and
- Debugging - seeing the information flow with `print(var)` at least. Exception handling at best! Mental comfort with things not working the first time is essential!
- Searching - Asking the right questions is very important when you encounter errors. Learned helplessness is pervasive, but you must fight against it.
- Modules - Since we've covered many modules, you should have an idea of what they are and how to import and use modules. You will need to use modules like `re`, `os`, `glob`, `pickle`, etc.

Projects can be fun, like advertisement level fun.
