

if you are using it, the timer statements). The counter variable is your main tool here, and the puzzle is to use this increasing number to do the repetitive (but slightly changing) tasks - such as requesting the data, naming of the files, accessing multiple entries of a data structure/variable, etc.

Between the request and action on the response, you can add checks for error responses, format consistency, some form of data format conversion - any problem that you can encounter as you iterate, or foresee. The parameters of this main loop will depend on your individual use case but you may also need to have a couple nested loops within your main loop, depending on if the data you are fetching has a nested structure. Tweak until satisfied. Build around it to make a general purpose text/file scraper. Compartmentalize into functions if necessary. Put it all in the `def main()`. If you want to geek out on the next level, make it a custom CLI tool with the `docopt` or `click` modules.

Tip: In most use cases, control flow can be adequately accomplished by just loops and conditionals (`for` and `if` statements). The loop takes care and control of the repetitive aspect of the task and the conditions allow for selective application of the particular actions of the task. You can use this fact for the following projects as well.

Control flow - the current state is the box pointed to by the finger, which travels along the arrows according to the actions taken
