

train of thought. Thus, like in a car, it makes sense to have the ‘go’ control of the speed reader designed like an accelerator pedal. Except that since the keys of the keyboard don’t have multilevel sensitivity, there will be no acceleration, just start/stop (press/default).

The main purpose of a speed reader is achieved by displaying the words in order, with a delay between consecutive words to allow for comprehension. You can print, pretty print, use tkinter, the text display method is up to you. Once you have this function working for any length of dummy text, change the delay variable to find a speed that suits you and work out a range for the fastest and slowest settings.

- **Step 3: Make Menu Mode**

A speed reader would not be complete without settings (and other controls and customisation) - put the display code from the previous step in a method in a Speedreader class. The reading display should occur when this function is called, using other class attribute values such as speed, font, etc. Give the method an escape key, in addition to the accelerator key (and perhaps rewind/fast-forward keys too). The escape key should exit the reader display and go to a main() function which will be your base of operations.

The main() method in the class will be a very simplistic menu. The objective is to display the available actions and current values of the settings and then ask for an input. According to the input the corresponding action will be carried out. For example “1 - choose file, 2 - set speed (wpm), 3 - change colour...” This can be achieved without the use of extra modules but you can also use click if you want.

Make the individual methods to change the ‘global’ values, such as def updateSpeed(n). Call these methods from the control flow in the main() method, according to the input menu. Settings should only be changed like this anywhere in the program - Every action or adjustable parameter of your program (you can give different fonts, sizes, stretching, alignment, decoration, transitions, and anything else you can think of..) will be carried out by a dedicated method, called when required.
