

Your average diode without the excess heat.

and running the same app when it is hot. The app will run comparatively smoother while the phone is cool as compared to when it is hot. This is because of the throttling mechanism built into the phone's SoC. When the temperature of the phone exceeds a certain threshold, the internal throttling mechanism kicks in and reduces the number of active cores or reduces the clock speed significantly. This allows the phone to continue functioning and cool down while doing so. Important note: we don't recommend that you introduce any external heat onto your phone. That would be ridiculously silly and potentially life threatening.

The excess heat generated also reduces the life of passive and active components. If you've ever read through a data sheet for any electrical component, then you might have come across a term called MTBF which
