

metal which acts a natural heatsink. Should you find that to be an issue for whatever reason or you wish to cool your hard drive “just because you want to” then there’s a water cooling block for your HDD needs as well.

You can get water cooling blocks for individual hard drives or you can get the one pictured here which cools three hard drives at the same time. Having such a unified water block saves a lot of space since you don’t have to have more piping between individual blocks.

## Power Supply

Another odd thing to cool is the power supply. We say odd because PSU coolers come in the form of giant slabs which are slapped onto the PSU externally. If you’re familiar with power supply circuitry then you’ll know that the components that tend to heat up are the voltage regulators which are often vertically mounted within the PSU. This is done so that passive heatsinks can be attached to the voltage regulators. The other components that tend to heat up are the DC-DC convertors which are also mounted in a similar vertical fashion.

PSU Water block affixed externally

Since the elements that heat up are not in direct contact with the surface that’s connected to the water block, the efficacy of the cooling block is greatly restricted. Hence, it ends up being more of a gimmick. If you really want a water cooled PSU, then opt for a PSU that’s water cooled by

design. Also, current generation of Power Supplies have become so efficient that most of them ship with a high fan-curve. So the cooling fans kick in only when it actually heats up under load.

## More

Well, if liquid cooling individual components is not your thing then you can certainly try out some of the outlandish cooling methodologies that we’ve seen in recent times. 3M has a fluid called Novec which has high thermal
