

coolants, you will be able to design a unique system giving it a personal touch. However, without appropriate knowledge about different tools and parts required to build such a custom cooling system, it could be wasted effort. There are numerous parts and factors that need to be considered before you make a buying choice. However, you'll be scratching your head if you go out buying all these parts individually. This is where you could go for custom loop cooling kits that provide you all the necessary parts in a single package. Let's have a look at the various components required to build a custom closed loop liquid cooling system.

Alphacool Eisblock XPX CPU
water block

Water blocks

When you're planning out your open loop liquid cooling system, you have to decide which components do you want to liquid cool. You already know that several components can be cooled within a loop. Out of them, as a beginner you would tend to liquid cool your CPU and maybe later include your GPU

in the loop. The water block's purpose is to dissipate the heat from your component into the coolant sent to the radiators to be cooled off. There isn't much to consider when you're buying a CPU block. All you need to check is whether it's compatible with the socket of your CPU. The same goes for the GPU block or any water block on a specific component. There can be compatibility issues with graphics cards since the PCB length might be different. You will need to buy the specific skew of the GPU block based on your graphics card. Hence, it's always best to go for the reference cards. Another thing to consider is whether you want to cool only the GPU chip or the other components onboard including the chokes, memory units and VRM. If you want to liquid cool all of them, you should go for a full cover GPU water block.

Coming to the material of the water block, you can choose from copper, nickel-plated and aluminium ones. Generally, you will find most of them
