

contrast the colour of your coolant that you've used in your cooling setup.

## Coolants

Looking for the right coolant or liquid can be overwhelming. The number of options and chemical names will confuse you further. Without delving into what every chemical does, we will explain the basics of what a coolant should have and what you should go for

based on your build. Coolants are generally a mixture of distilled water along with additives (antimicrobial and anti-corrosive) and colour dyes. As a beginner, we would recommend starting off with just distilled water and avoiding coloured dyes completely. Since they tend to have different

chemicals, they will cause problems from your first build. However, only distilled water won't make the cut and you will need to add antimicrobial additives to prevent the formation of algae in the loop. These additives are Silver strips called Kill Coil and Copper Sulphate also called Bio-cide. As we already mentioned that introducing different metals will lead to corrosion eventually, so if you're going with distilled water, you should consider small amounts of Copper Sulphate. If you want to completely avoid this problem, then the other alternative is a mix of Propylene Glycol along with some additives. This is usually sold by liquid cooling product manufacturers with dyed variants. Otherwise, you can buy dyes separately for your distilled water setup. If you don't want coloured dyes, then you can go for coloured tubing. Going with either of these will let you customise the cooling system according to your preferences without taking away from the performance, or enhancing it at all.
