

Keeping it cool

Heat is the natural enemy of all electronic components and your PC is no different. Thankfully, there exists a plethora of options for you to cool the various components within your PC. You're no doubt familiar with CPU coolers and even All-in-One liquid coolers, and perhaps you'd even love to have your own fancy custom liquid cooling loop. Most of these coolers are built for cooling your CPU and graphics cards. However, did you know that RAM, hard drives, SSDs and even power supplies can be liquid cooled as well? And if this was outlandish, then how about submerging your entire PC in a vat of coolant?

If that got your attention, then we're sorry to say that we'll not be performing any such outlandish cooling experiments, however, we will be exploring the common ways that your CPU and GPU can be cooled and get into the nitty gritty of these devices. This way, you'll understand what each and every component on your average CPU cooler does and how important it is at the end. We don't stop with just that – we'll take it one step further and teach you how you can keep your CPU cooler working in top condition for the rest of its life.

All of the above is just one half of this FastTrack, the remainder is dedicated to building a custom liquid cooling loop. Yeah, we went there. We might not be performing outlandish cooling experiments as we mentioned earlier but we can certainly help you realise your aspirations of having a custom loop in your personal computer. You'll learn about the different components used in a custom cooling loop and why they're important. Since, custom loops have a significant DIY element to them, we'll take you
