

Ball valves allow you to control the flow of the liquid

Apart from the essential fittings, there are optional ones that can be considered for specific builds. If you're using hard tubing, especially metal tubing, then bending them won't be an easy job without the appropriate tools and you might end up damaging them. This is where you use different types of angled joints that will take care of the bends at angles of 45 and 90 degrees. You might even need T-splitters or X-splitters if you want to connect multiple tubes. Ball valves are also available when you want to control the

flow of fluid. This is usually used for drainage but some reservoirs will ship with a ball valve anyway. If there isn't a drainage valve, you can use a T-splitter and connect one end to a ball valve and have your own drainage valve. You can also buy extensions and pass-throughs in case your tube falls short in length. Using them, you can connect two tubes.

Tubing

Primarily, the tubing that you can install can be soft or hard. Soft tubing is generally made from PVC and being flexible, it is easy to handle. You won't have much problem cutting them and they aren't that expensive. However, since they tend to slack, they don't really look that good. This is where hard tubing comes in. They offer insanely good aesthetics on a built system because of the numerous bends that can be created
