

In no particular order, let's talk about thermal pads. Before you run off and install them over your CPU or GPU, you must know that they aren't here to replace your thermal compound or paste. Instead, they are generally used to cool the other components on the graphics card including the chokes, memory units and VRM. So, you'll be buying thermal pads only when you're planning on liquid cooling your graphics card. At times when you aren't sure if the block and GPU are going to make good contact, you could go for thermal pads to fill the gap. However, if you're certain that there won't be much of a distance between them, then you should definitely go for thermal compound. After disassembling the chassis, you will find coloured tapes over these components that just do the job of heat dissipation. If your

Thermal pads installed over all the components that require heat dissipation

GPU water block covers these components, you should be replacing the default thermal pads with new ones. You should be looking at thin pads since thick ones perform poorly. Apart from graphics card, they can be attached to M.2 SSDs as well.

For the tubing, you can buy various parts for a clean design, especially when you're dealing with soft tubing. Since they tend to slack, you can use clamps to attach them at different parts of the chassis. Do note, that you will need to match the OD of your tubing with these clamps. Another problem with soft tubing is the formation of kinks. Kinks are the tight bends that occur
