

Using a bundled cleaning kit will give your custom loop a deep cleanse

While you spend time cleaning the insides of the tubes and water blocks, you should also pay close attention to the smaller fittings. A lot of residue tends to form around the threading of most of the parts. The fittings and radiator tube valves also need to be cleaned thoroughly. Use the same soft toothbrush method to clean them with warm water. Take your time to rid the fittings of any form of residue or gunk.

Although disassembling the parts and washing them can be considered deep cleaning, a step ahead will be making the use of chemicals in cleaning kits. You can either buy these chemicals individually or go for kits like the Mayhems Blitz Cleaning Kit. These cleaning kits will clean the insides of the tubing, radiators and reservoir and prepare your custom loop for a fresh coolant. Going this route would be better solution if you're switching to a different type of coolant and don't want any residue from the previous coolant. There will be different cleaning agents for the process to get rid of rust using something acidic and then something to flush everything out.
