

Overclock.net user Teh Noob Slayer cleaning the radiators after algae formation

Since it's deep cleaning, it's recommended to keep the fluid circulating for around 12 hours.

With all the cleaning done, it's time to refill the custom loop with new coolant. No matter what, don't pour in used coolant. Based on what coolant was used in your system, you need to read their specific instructions on how to dispose it off since it could be toxic.

Radiators and fans

Using radiators and fans to cool the coolant will lead to dust accumulation over time. Even if you have a dust-free environment, the constant air intake or exhaust (based on your fan configuration) will build up dust eventually and start clogging the airflow. The only way to reduce dust would be using dust filters on the case since you can't completely avoid it. In order to check whether dust is clogging up the radiator fins, you have to remove the installed fans. If you find too much dust build up in the fins then you should definitely blow out the dust. Otherwise, you can simply brush off the dust with a small and soft brush. Make sure that you don't damage the fins in the process. Hard tubing or soft, we'd recommend you to remove the radiator from the system while cleaning. Even slight bumps and movement
