

can lead to cracks or loose connections in the tubing which can create an unnecessary mess. After you're done with the radiator, you should clean the fans too. The blades tend to accumulate dust that might hinder with the fan's speed if it starts forming a thick layer around the bearing. If it gets worse, the fan might not even be able to rotate properly with all the gunk around it.

Cleaning the radiators and fans shouldn't be a time-consuming process. The most effective method would be using a vacuum cleaner to blow the dust away from the fins and the blades. Because of moisture in the air, the dust might stick to the components and form chunks inside the fins and under the fan blades. A vacuum cleaner won't be able to get rid of the sticky gunk deep inside the fins and you'd have to give the radiator a wash. You can use a water hose to remove the dirt or you could hold the fins under running warm water from a tap. Ensure that you've covered the CPU block with plastic. You wouldn't want water to fall on it. Running water might just do the trick but if the gunk puts up a fight, you can use a soft brush. Do note, you need to gently brush the fins since they bend easily. You will also need to flush the radiator in case there's some fluid left inside. This can be easily done by attaching two flexible tubes in the radiator with the appropriate fittings and pushing water into one while the other end flushes it out. Give it a few runs and the insides should be clean by now. After all the cleaning has been done, tilt and drain any water that might have entered the radiator. Use a hair dryer or leave it for several hours to dry. Only after you're sure that it's completely dry you should install it back into the system. **d**
