

to sub-zero level. In this chapter, we aren't only going to explore methods where you'll be pouring liquid nitrogen over your CPU or drowning your components in mineral oil, we are going to cover all the crazy methods by which you can cool your PC and keep it running. Here are some of the extreme ways of cooling your PC in no particular order that will definitely make people's heads turn.

Liquid nitrogen

Starting off with probably the most popular one in extreme cooling is liquid nitrogen. You must have already seen pictures or videos of overclockers holding a thermos and pouring a liquid into a cylinder over a motherboard. Also called LN2 or just nitro, the liquid needs to be constantly poured in the CPU pot in order to maintain a constant temperature. The reason LN2 is used for cooling is its extremely low boiling point at -196 degrees Celsius. Hence, as soon as it's out of the container, it boils up in room temperature. This is why it has to be poured continuously into the CPU pot while the
