

Geothermal cooling

Another extreme way of cooling your PC (not to extreme temperatures) would be taking the help of mother Earth. Geothermal cooling is a different ballpark for cooling your PC. But there have been few people who have successfully done it in their own backyards. The principle is the same as liquid cooling. However, the difference here is that the heat exchange happens underground. Instead of using a radiator, the tubing has to be buried to a suitable depth to achieve the desired temperature. You probably know that as you dig deeper into the Earth, the temperature drops. The depth at which you will find the favourable temperature will vary based

Geothermal coil loops being buried 12 feet underground

on your location. It could either be just four feet below or even twelve feet. Sometimes, you might also come across water at such a depth. The heat exchanger in this case, pipes in several loops, is buried at the appropriate depth. And the liquid is water. As a small project, you can go with plastic or Nylon pipes but if you want to take things to the next level, then you should opt for insulated copper pipes in the form of geothermal coil loops. The idea is to achieve enough surface area with as many loops possible to have uniform and efficient cooling. In this system, you're going to pull water from a depth, so you will need a full-fledged water pump, the likes generally used to raise water to overhead tanks. The rest of the system remains the
