

same. Your tubing connects to the pump from your components and the pump connects to the loops underground. What is happening here is that you're using the cool temperature below the earth to cool down the water and using the same cooled water to cool down your components. So cool! The only challenge is whether you're willing to take up so much physical labour to build this system.

There's another workaround to this method if you don't want to spend on geothermal coil loops. Instead, you can replace it with a storage tank and bury it underground. The water inside the tank will cool naturally because of the low temperature down there. Rest of the contraption remains the same. The only problem here would be that the tank has less surface area in contact with the ground. Although the temperature will be low compared to the surface, it won't be as efficient as using geothermal coil loops. **d**
