How to use the Game View

The Game View is generated from the camera and it emulates the final published game. Unity recommends you to make use of multiple cameras so that player will be able to control the games effectively. The Game view can be used to test drive the game before submission and hence you will be able to experience the look and feel of the game as if you are playing in the real-world. You can use the Play mode button located on the Toolbar to control the game. Moreover, you can actually visualize how the published game will look for an end user.

Unity provides Game view control bar with several options using which you can modify all the parameters. The Display option enables you to select a camera from the provided list if you have multiple cameras in the game scene.

With Aspect option, you can choose the resolution of the game that you need to simulate. With the rapid growth in several new aspect ratio devices, it is essential for you to test the game under various environments and use cases. The editor provides different aspect ratios for various devices. The default setting is Free Aspect but you can test drive the game by changing the values. The editor provides options such as 5:4, 4:3, 3:2, 16:10, 16:9 including the standalone resolution of 1024x768 pixels.

You can use the scale slider to examine critical areas of the game by zooming in. The default value is 2x but you just need to move the slider to the right to change it. As a game developer, you should examine the condition of your game when in full screen mode by using the Maximize on Play
