

Understanding Toolbar

The Toolbar consists of several tools using which you can work with the active scene. The Hand tool is used for panning around the scene and is located first on the Toolbar. You can use the remaining tools such as Move(W), Rotate (E), Scale (R), Rect Transform (T) and Transform (Y) to edit the relevant GameObjects. You can provide values inside the Transform tool number field to alter its functionality. It is also possible to activate the transform modes using hotkeys as mentioned in the braces above.

Move

If you select Move from the Toolbar, you will find three small squares on the centre of the Scene View. You can use these squares to drag the GameObject within a single plane. It is possible to move two axes while keeping the third axis as such. The centre of the Gizmo changes to a flat square shape if you press shift upon clicking and dragging in the center of the Move Gizmo. The purpose of the flat square is that you can move the GameObject around on a plane according to the direction of the Scene View camera.

Rotate

As the name suggests, the Rotate tool is used to modify the rotation of the GameObject. It can be done by clicking and dragging the axes of the wire-frame sphere Gizmo. If you changed the last axis using the Rotate tool, it will be coloured Yellow. The Red, Green and Blue circles are used to perform rotation around the respective axes. You can easily rotate the GameObject around the z-axis by using the outermost circle.

Scale

The Scale tool enables you to rescale the GameObject evenly on all axes. You just need to click and drag on the cube located at the centre of the Gizmo.

RectTransform

You can work with the RectTransform tool to position 2D elements such as UI elements and Sprites. However, you can also use them to manipulate 3D GameObjects. The main aim of the RectTransform tool is to bring all

Define the location of the tools easily
