

The purpose of the Object Picker is to enable you to select objects within the scene or assets included with the project. It is possible to pick a reference property just by double clicking the same from the picker. The values are assigned by providing relevant values inside textboxes, menus and by enabling/disabling checkboxes. However, you will have to work with dedicated editors for certain specific values such as Colors, Gradients, Curves, and Arrays.

The Unity editor includes Color Picker using which you assign colours to the objects. If you are using Mac, you can work with the system picket by navigating to Unity>Preferences menu. The Curves editor helps you to work with animations. It renders a line graph that corresponds to X (value) and Y (response) axis respectively.

The Gradient editor helps you to provide a visual representation of a colour progression. The editor displays main colours with all possible shades. The editor includes upward arrows that denote the stops. If you select a stop, the resulting value will be shown in the Color box located below the editor. If you click on it, you will view the standard colour picker. You can create multiple stops and can also change the position of the stops by dragging on it. It is also possible to remove the stop by using the keyboard shortcut Control+Delete. You have to use Command

button in case of Mac. If you look at the top of the editor, you will be able to see down arrows that signify the alpha of the gradient. The Gradient editor includes two stops that are configured to 100% alpha.

The Inspector window includes a value editor, which enables you to not only modify the size of the array but also values or references. The values emerging from the end of the array will be removed when you attempt to decrease the Size property. The value will be modified depending upon how you change the size. For instance, you can configure the first element and change the size. The corresponding variables will be copied to all other elements.

The Unity editor is developed to reduce the overall development time. You can select multiple objects and edit the common components shared by the selected items. You just need to provide values once and they will
