

and hit enter or return to confirm your choice. Remember, a plane has no volume and thus scale does not work on the Y-axis. There will be no change unless you go into negative numbers, in which case the plane will simply face the other direction. If you place a plane in the scene and you can't see it, check your orientation between the plane and camera and make sure that you have the correct values for the Y-axis of scale. (Usually the value of 1.)

Player Object

Now let's create our player object. Here our player object is a Unity stock sphere. From the menu select Hierarchy > Create > Sphere. Rename the sphere to Player. Reset the transform to make sure it's at the origin. Select Edit > Frame Selected, or use the F key while the cursor is over the Scene view, to focus our Scene view camera on our game object. Now is the sphere buried in the plane? This is because both game objects are in the exact same location in the scene, the origin point, or (0, 0, 0) on the X, Y and Z-axis. We need to move the player's sphere up until it rests on the plane. All Unity primitive objects, cubes, spheres, capsules, have a standard size: they are either 1x1x1 or 1x2x1 Unity units. So we can simply lift the player object up by half a unit in the Y-axis and we know it is laying perfectly on top of plane. If we look in the Game view, we can that the player game object is lit and it casts a shadow on the plane.

All new Unity scenes come with the default sky box and a directional light to represent the sun, so we don't need to worry about setting up any default

A new sphere will share the origin point with the plane.
