

Movement

Moving the camera and the player

Now we are going to move the player game object. First let's think through how we want this player object to behave in the game. We want to have the sphere roll around on the game area, bump into walls, stay on the ground and not fly off into space. We want to be able to collide with our collectible game objects and pick them up when we do. This requires physics. To use physics the game object needs a rigidbody component attached. To attach a new component we must first select the game object we want to attach the component to, in this case we will select our player game object. Then we can either choose the Component menu and select Physics - Rigid Body which would attach this component to the game object we have selected. Or use the Add Component button in the Inspector choosing Physics - Rigid Body. Either way this attached the rigidbody component to the selected game object. If we choose to we can rearrange the order of the components on the game object
