

There is a shortcut in Monodevelop that searches the Unity API. On the Mac, it's command plus single quote, and on the pc it's control plus single quote. Select the item you want to research, in our case input, and hold down the command or control key and type the single quote button. This search brings up every reference in our documentation related to input. Select Input at the top, interface in to the input system. This brings up the page on Input. This is the page on the input class. We use this class to read the axis setup in the input manager and to access multitouch touch and accelerometer data on mobile devices. We read the text on the top of the page to understand how to use the class. In our case, to get input from the player on all platforms, including mobile devices. Under the description is a list of class variables and class functions. The class variables hold information like the number of touches in touchCount or a reference to the default gyroscope with gyro. The class functions do something for us. In our code we will be using Input.GetAxis. When we find the item we want we click on the link to bring up a page on the function or the variable. Let's look at Input.GetAxis. This page includes the signature of the function, a description of the function and code snippets showing how to use it in Unity's Javascript and C#. We will be using C#. We will be using Input.GetAxis in a very similar way to the code snippet.

Fine tuning the script

Let's return to our script and write our code. float moveHorizontal = Input.GetAxis("horizontal") float moveVertical = Input.GetAxis("vertical") This

Using the GetAxis input
