

The ball moving in the scene, but is too slow.

reference. And in a new start function we need to write `rb=GetComponent` In `FixedUpdate` let's use the simplest version of `Rigidbody.AddForce`. One that simply uses a `vector3` and we will leave the `ForceMode` at default by omitting it from our code. So in our script we need to type `rb.AddForce` and then some `vector3` value. No how do we get our two float values in to a `vector3` value? Let's create a new `vector3` variable called `Movement`. This will be equal to a new `vector3` that is made up of an X, a Y and a Z. The X, Y, Z values will determine the direction of the force we will add to our ball. What is our X value? That would be `moveHorizontal`. With this our left and right keys will add force moving the ball to the left or right. What is our Y? 0. We don't want to move up at all. What is our Z value? That would be `moveVertical`. Now we use `Movement`, a `vector3` value, in `rb.AddForce` as `rb.AddForce(movement)`. Let's save this script and return to Unity. We check for errors in our footer or the console and there are none. Good.

Testing the input

Let's test what we've written. Hit Play, and by using the keys setup on the input manager the ball moves in the scene. But it's very slow. This is too slow to be playable, but the basic concept works 100%. To stop testing leave play mode. Let's return to our code and create a tool that will give us control over the speed of the ball. We need to multiply our movement by some value. We could simply enter that value here on our script but if we ever needed to make any tweaks or changes we would
