

The camera behaving erratically in Unity.

camera's point of view rotates with it. Let's exit play mode. Unlike a normal third-person game our player game object is rotating on all 3 axis not just 1. In a typical third-person setup the camera as a child of the player game object will always be in a position relative to its immediate parent, and this position will be the parent's position in the game, modified or offset by any values in the child's transform. We can't have the camera as a child of the player, so let's detach it. Our offset value will be the difference between the player game object and the camera. Now we need to associate the camera with the player game object, not as a child but with a script. Using the Add Component button choose New Script. We are writing in C# and name the script CameraController and then click on Create and Add or simply hit the return or enter key to confirm our selection. We should note, this way of creating a script will create that script asset on the root or top level of our project view. File CameraController in the Scripts folder and open it for editing. We need 2 variables here. A public `GameObject` reference to the player and a private `vector3` to hold our offset value. Offset is private because we can set that value here in the script. For our offset value we will take the current transform position, and subtract the transform position of the player to find the difference between the two. So in start we can make offset equal to our transform position minus the player's transform position. And then every frame we set our transform position to our player's transform position plus the offset. This means as we move our player with the controls on the keyboard that each frame before displaying what the camera can see the
