

Creating the walls for the play area.

be improving by adding boundaries and collisions. The movement of the ball has also been set up. However, it will simply fall off the play area and keep falling forever if there are no boundaries. The sphere can move anywhere but there are no confines to it. So to add in confines, we put in walls. Just like you added the plane and the sphere, walls are also added through GameObjects. This is one of the most important tool in Unity Editor, which we will learn about in detail in a separate chapter. GameObjects represent characters, props and scenery. They do not accomplish much in themselves but they act as containers for Components, which implement the real functionality. The basic components include the Transform tools. Under this, you can position the wall in the game, specify the rotation and scale it for height, length and depth.

To start creating walls, create a new game object and rename it Walls. Be sure that you reset this gameobject to origin. This is necessary to facilitate easy placement of all the walls that you create henceforth. At this point, this is an empty object which you can use as the parent directory to hold all four wall objects. Organising the gameobjects hierarchy is just as important as project hierarchy.

To create walls, create a cube, rename it West Wall and reset it to origin. Put it under the Walls folder by dragging it in the Hierarchy window. Now as you edit this cube and transform it into a wall, you need to be able to view it in a better way. Focus the scene view camera to the West Wall object. Now you can see the cube up close.
