

to the assets, use the physics engine, map keyboard inputs to actions in the game, control a virtual camera, design a simple UI that reacts to how you play the game, and finally export the completed game to a target platform. You do not need to stop there though, using the same principles that you learned, you can create a more elaborate ball rolling game, with platforms, puzzles and levels. The same principles can be applied to create other kinds of titles, dungeon crawlers, or action shooters. Creating the assets yourself does require some proficiency in 3D and photo editing software. This Fast Track does not go into the details of producing the assets themselves, but focuses on creating the game itself. In the second part of this Fast Track, we will be showing how to make a 2D game.
