

representations in Unity- Quaternions or Euler angles. Internally or in scripting, Quaternions angles are used but in the Inspector window, Euler angles are displayed. This is because Euler angles have only 3 angles of inputs of X, Y and Z axis which make them easy to understand and interpret. On the other hand, Quaternions have a fourth dimension W. All the four dimensions of Quaternions don't represent angles or axes and hence you won't normally need to access them directly. A Quaternion can represent either an orientation or a rotation - where the rotation is measured from the rotational "origin" or "Identity". Because the rotation is measured in this way, from one orientation to another, a quaternion can't represent a rotation beyond 180 degrees. In spite of the drawbacks, internally Quaternions are used as the benefits far outweigh the negatives.

Lights

You have worked with a global, default light earlier. But you might want to add in an extra light or lights to make the game jazzy.

Got to GameObject ---> Light menu and choose the light format that you want from the sub-menu that appears. Post this, you can edit it like any other GameObject. Additionally, you can add a Light Component to any selected GameObject by using Component ---> Rendering ---> Light.

There are many different options within the Light Component in the Inspector window like changing the light colour etc. Play around (no pun intended) with the different settings and see what effect it has on the game and game play.
