

and return to Unity. The next step is to test. Enter the play mode and check if the Pickup object is working on all the properties you have assigned it.

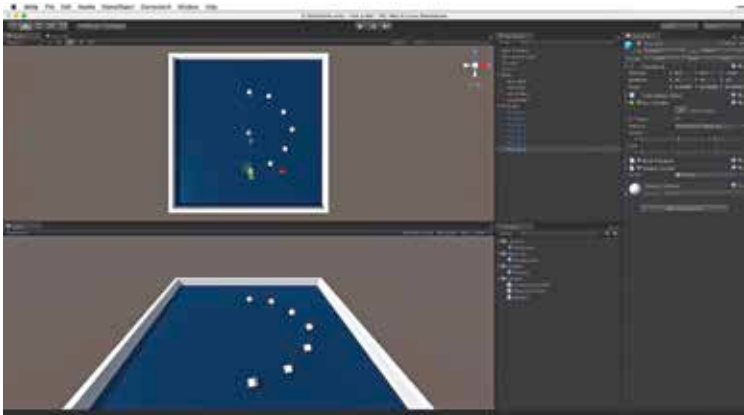

Making it a Template

A template is assigning a set of properties that can be used repeatedly and will be applied to anything created with that template. In Unity, a template is called Prefab. So a prefab is an asset that contains a template or blueprint of a game object or game object family. We create a prefab from an existing game object or game object family, and once created, we can use this prefab in any scene in our current project. With a prefab of our Pickup object we will be able to make changes to a single instance in our scene or to the prefab asset itself and all of the Pickup objects in our game will be updated with those changes.

First step is to create a folder that will house the prefab and that it should be on the root or top level of the project. Ensuring that no other item or directory is highlighted, select the project view and click on Create --> Folder. Name this folder Prefabs and drag and drop the Pickup object from Hierarchy window to the newly created Prefab folder. Dragging an object from the Hierarchy window to Project view does not remove it from the Hierarchy window. It simply creates a template in the Prefab folder of Pickup object with its current properties.

Duplicating

Create an empty game object in the Hierarchy window called Pickups and

Duplicating the collectible game objects
