

detected, the object is picked up by the player. Simple enough? Let's begin then.

There are two aspects - these collisions should trigger a new behaviour and they should be tested to make sure that the correct objects are being picked up. The testing part is important because without it, all the objects including the walls will be picked up since every object contains colliders. These colliders send signals to the game engine that a collision has occurred.

At this point you should remember that you had deactivated the player object to create the pickup objects. Time to get the player back. So just tick the Active check-box. Next select the PlayerController script and open it for editing.

One way that you have already seen is to type in collider in the script editor and then go to the Scripting Reference page. Now let's look at another way. Look at the sphere collider component. On the top of this section, on the left, you will see a turndown arrow, the icon, the Enable checkbox if it's available, and the type of the component and on the right is the context sensitive gear gizmo and an icon of a little book with a question mark. Click on this book icon and the reference manual will open. Switch to Scripting manual and you will see the scripting for the sphere collider. Using the code `OnTriggerEnter`, you will be able to detect the contact between the player gameobject and the `PickUp` gameobjects without actually creating a physical collision. Copy the code (the one that starts with using `UnityEngine`) from the reference, paste it in the editor and correct the indents.

Adding colour to the pickups to make them more attractive
