

that are required in the project but should not be a part of the final game as viewed by an individual. If you build without including any scene in the pane, the current scene will be used to build the game.

Below this pane, you have the platform pane with platform details next to it. Below these, there are options to switch platforms, access the player settings, build settings, build and run.

With the Build Settings window open, drag and drop the relevant scenes in the scene selector pane. Note that the scenes are indexed in the order you dropped them. Scene 0 is the first scene that will be loaded when you build the game and so on and so forth. You can rearrange this list by simply selecting and dragging the scene to the required position. You may want to keep Scene 0 as the splash screen. The splash screen displays promptly, displaying while the first Scene loads asynchronously in the background. So you can display some nice, engaging content like some artwork while the rest of the scenes load while running the game. To remove a scene, highlight the scene and press Command+Delete or Ctrl+Delete.

Once you have included the relevant scenes, move on to the platform selector pane. The selected platform will display the Unity logo next to it. By default, the PC, Mac and Linux standalone platform is selected. To build to any other platform, highlight the platform and click on switch platform. You may not be able to build to certain platforms if you have not downloaded the necessary files like iOS or some like PS4 may require special licenses. You can see the platform details for the one selected in the right hand

The different build target platforms available in Unity
