

Running the game that you have built.

to install the game. If you are building for Mac, an app bundle will be built which contains the file needed to run the application as well as the resources. If it's PC, an executable file (.exe) will be built, along with a Data folder which contains all the resources for your application. To distribute or deploy the game you will need to send all the files built by Unity.

The building process will place a blank copy of the built game application wherever you specify. Then it will work through the scene list in the build settings, open them in the editor one at a time, optimise them, and integrate them into the application package. It will also calculate all the assets that are required by the included scenes and store that data in a separate file within the application package. Any GameObject in a scene that is tagged with 'EditorOnly' will not be included in the published build. This is useful for debugging scripts that don't need to be included in the final game.

Congratulations! You have successfully created and built a game ready for deployment to be enjoyed by others. Take a moment, play your own game, win and pop open a bottle of bubbly. **d**
