

WWDC17 is where the launch of ARKit was announced. Google's ARCore was announced a few hours later.

As far as ARKit mobile apps go, they are compatible with any model of Apple phones that are iPhone 6s and upwards. That number would easily be in millions if not billions. With Google's ARCore, they began by applying the tech to their own Pixel devices as well as flagship phones from other manufacturers as long as they were supporting Android 7.0 or 8.0.

The release of these SDKs (software developer's kits) has definitely been a welcome addition for developers because both SDKs come with implanted features that are native to their respective OS. This negates the need of creating specific AR mobile apps that can harness the hardware found on Android or Apple devices.

## Features of Both SDKs

Currently both SDKs ARKit and ARCore are in their nascent stages. From the perspective of application products, there is almost nothing to differentiate them.

- Both recognize horizontal as well as vertical surfaces on which virtual objects can be displayed or placed
- They take lighting conditions in the physical environment into
