

SLAM tracking augmented reality apps exist that let you see if you have a stalker lurking in the bushes

Additionally, both ARKit and ARCore support the following -

- Geolocation and SLAM mapping tech
- World and facial tracking
- Cloud and on-device marker storage

### So how are ARCore and ARKit different?

While the list of features mentioned above will tell you what both these platforms are capable of, it does not really help you make a choice. If you are looking to know the pros and cons for each of these SDKs, read on.

Now would be a good time to reiterate what we said earlier - the differences in capability of both these platforms is extremely subtle and almost negligible. The attention that has been paid to features like lighting estimation, motion sensors, etc make the entire alternative world aspect come to life with AR apps developed using these SDKs.

As far as mapping is concerned, ARCore does seem to have the upper hand. This is thanks to its ability to manage and remember larger maps. ARKit apps store data that is most recently captured, thus forcing the user to 'rediscover' areas that were not in the camera's view of field any more. This could be quite a hassle if say, one were to drop their phone.

ARCore apps also have another hidden mapping advantage. Reports say that Google allows for a mapped area to expand more quickly. That being said, ARKit does seem to have the upper hand when it comes to accuracy in
