

ARKit is Apple's tool to create AR apps and projects.

- Start by clicking on File in Xcode, then New and select Project.
- You'll be met with a list of options. Click on ->Augmented Reality App and filled in the details for the AR app project in the respective fields.
- You can name your AR app anything you want. You can also choose to distribute sharing rights for the app by selecting whether to work as a team or to execute it individually.
- On clicking next, you'll be prompted to select the language for coding the environment in the language option. Users have the choice between Swift and Objective-C that's powered by Cocoa extensions. Take note that Swift is a more advanced version of the software and can support multiple operations at the same time while Objective-C is relatively old.

Apple ARKit On An iPhone

Users of python would feel right at home with Swift due to its simplicity in commands, syntax and keywords. Take note that Swift is again only available for systems on Apple operating systems but can be worked on Windows and Android devices by using a nifty little emulator.

Finally, you can choose your "Content technology". This relates to the various windows where the AR content can be developed. If you hover over the top alt bar, you can see that there are windows for- SceneKit, SpriteKit, and Metal.

These is nothing but different rendering engines for displaying graphics. All three are useful for building AR apps but come with their advantages
