

- Choose the item that you want to integrate to the scene and then press the Home symbol to bring more and more items from the search bar. You can keep importing the items as needed.
- Then search for the “UnityARKitScene” scene in the Unity ARKitScene folder under the subfolder “Asset/Examples”.
- Drag the scene from the “UnityARKitScene” filed under Hierarchy. Go to the assets and just search for any item.

Designing In ARKit Through Unity

- Go under Model and drag the item under Hierarchy and then click HitCubeParent. You will see that the environment has capabilities for moving in the 3-dimensional space as well as generating random shapes.
 - Remove the default HitCube and RandomCube from the scene by right-clicking and then hitting Delete. Click on the GeneratePlanes button, ARKitControl, and click on the inspector and uncheck Tag.
- Congratulations, you’ve just got your first AR item out in the open.
- Next move on to the Main Camera window and click on CameraParent and in Inspector, set the Near option to a distance of your choice. Let’s say 0.05.
 - Click on the Scene tab. Click on the item you want to render by clicking it from the Hierarchy tab to select it. This brings the item in Scene view in three-dimensional space.
 - If you’re interested in knowing the script for the same, then go to the asset option UnityARKitPlugin and then click on Plugins and finally Helpers. This generates a sample cs script. Drag this script into the inspector window and view the code.
 - Drag the item in the Hit transform field of the cs script window, and you will see it come to life. Save the scene by clicking on File and then Save Scenes with a suitable file name.
 - It’s now time to dust off and watch this on the iOS device. Go to the File menu and choose the Build Settings. Click on Platform and select the device that is connected. If not connected, configure the device and recheck its status in the Xcode environment.
 - Press the Player Settings button and click on Bundle Identifier. Create an identifier of the type: “com. <File> .Filename”.
 - Click the Build button in the Build Settings window and save the AR project. Finally, locate the XCode project in the Finder named “Unity-iPhone.xcodeproj”.
