
Setting up ARCore

- Double-click it to open the project with XCode and scroll to the General option. In the field, type down the same Bundle Identifier used in Unity's Build Settings.
- Select the device for configuration and press the XCode arrow key to lead to "Build and Run the Current Scheme". And from here on you will view the item on the device in full detail. Make sure that the box "Show as run destination" is clicked from the Windows tab.

If the system fails to identify the same, then provide user preference rights to the device to view the AR object. And that's how you get going with your project on ARKit.

SETTING UP ARCORE

ARCore by Google is still under updated changes and is compatible even on the newly released Pixel 2. Google's major projects for AR were mainly created on the Tango platform and included some rather nifty additions for accurate identification of the surrounding environments.

ARCore Mainframe

Only a limited number of phones can support the capabilities for the ARCore environment- Asus ZenFone AR and the Lenovo Phab 2 Pro.

However, the good news is that these capabilities have been transitioned perfectly to the ARCore setup and mainly requires only a colour camera. ARCore supports most devices including the Android 7+.
