

scene into the build by clicking on the option that says Add Open Scenes in the window.

- Open up the Player Settings to change the settings that have been defined by Google developers:-
 - Turn off Multithreaded Rendering.
 - Go to Other Settings and Package Name and create a unique app ID that looks like a Java package.
 - Set the Minimum API Level to Android 7.0 or higher
 - Set the Target API Level to Android 7.0 or higher.
 - Turn on ARCore support for XR Settings.

The next objective should be detected and visualising planes that ARCore identifies in the system during real-time renderings. This will help you to place objects in the environment on the fly without many complications as well as less cycling speeds on the CPU.

Unity Package Details

Moving on, you should consider getting some scripts and prefabs that are useful for any ARCore app. Pull down the ARCore Device prefab from the GoogleARCore, then move the Prefabs folder to the scene where you'll find two important things:-

Session Component (Script):- This manages the connection to the ARCore session and analyses the scene by creating a device-specific configuration of all the elements like shading, shadow effects and camera angles. Most of the settings are hard-wired in the script and will change in the future versions of the SDK for updates.

First Person Camera:- The handy Unity camera, which contains a few pre-set settings ideal for ARCore. You can click on the details in the properties tab and change parameters like distance, resolution and angle.

Next, set up the environmental light in the scene by using the Environmental light option from Prefabs and configure the lightning estimation performed by ARCore. You can scale the intensity of the light or the colour by using the shader and change how the light should appear- sun, point, hemisphere or disc. To place objects in the environment, prepare the prefab of the object to place in the real world. Import your model by dragging and dropping it to the assets and then straight to the scene.

- Start by creating an empty object and name it. Just like Unity setups, you can place models and parent values as per the configuration. Once
