

Placing your object in the AR world.

you place the object, the ARCore mainframe will detect it in the real world and update the plane's location.

- To create more elements for the items go to Assets, then click on GoogleARCore, Scripts and choose the scripting of your liking. You can drag this script onto the main object window.
- Finally, create a prefab for the setup by clicking on Create and then clicking on Prefab.
- Move to the Hierarchy panel causing the object placed in real time to turn blue which should indicate that the object has been selected from all vertices and nodes.
- After doing so, check the rootkit for any scripting changes to the objects that will allow you to see how the system responds to changes in real time while the user drags and drops items.
- After the prefab has been created, you can safely delete it from the hierarchy. You can now work on projects for AR.

PREPPING FOR FUTURE PROJECTS

And so we arrive at the end of the setup procedures for both ARKit and ARCore. Differences may hinder early learners from choosing what environment to work with, but it's safe to say that both are comfortable for any capable programmer.
